\*These samples were taken to confirm previous grab sample results.

The copper mineralization is spread over a wide area. There are no bedrock outcroppings on surface. The only bedrock reached is in the main pit. As the sampling approaches the water table, chalcopyrite starts to appear and the copper values increase. Gold displays a nugget effect but appears to be enhanced with sericitic alteration as well as a second stage of silicification. The mineralizing history appears to be very similar to Ivanhoe's Turquoise Hill in Mongolia.
